Abstract

The invention relates to a method for operating a drive train having a drive machine and an automated variable speed transmission. In selected situations, for example when there is a change in the gear speed of variable speed transmission, it is advantageous calculate the profile of the rotational speed of the drive machine in advance. For this purpose, pre-stored profile parameters, for example in the form of gradient values when changes in rotational speed are requested, In order to permit a particularly are corrected. accurate calculation in advance, the corrected gradient is determined as a function of a requested difference in rotational speed. Alternatively, in addition to a corrected gradient it is possible to calculate corrected reaction time and to carry out calculation in advance by means of these variables. The reaction time is obtained as a time difference between actuation of a significant change in a state variable, for example a rotational speed, of the drive train. If changes pre-stored values are available, in rotational speed can be requested and the resulting gradients and/or reaction times can be stored.
